Mechanism of non-linear space-charge polarization in solid dielectrics

The nonlinear kinetic phenomena during shaping of volume-charge polarization in hydrogen bonded crystals (HBC) is investigated by the methods of quasi – classical kinetic theory. From the solution of the nonlinear system of equations, Fokker – Planck and Poisson, in case of blocking electrodes, it is established that the mathematical description of the relaxation of polarization in HBC, in the region of weak fields (100–1000 kV/m) and high temperatures ($T > 350$ K) linear approximation of the perturbation theory is sufficient. The coefficients of diffusion and mobility are calculated with respecting of both transitions mechanisms (thermally activated and tunneling) of the protons through potential barrier of parabolic shape. Proton - proton and proton - phonon interaction is not considered. The proposed scheme for solving the kinetic equation can be applied to other, similar to the HBC type and properties of the crystal lattice crystals with ionic conductivity.

Keywords: proton semiconductors and dielectrics; hydrogen bonded crystals (HBC); proton relaxation and conductivity; non-linear system of equations of Fokker - Planck and Poisson; relaxation modes; polarization frequency harmonics.

Introduction

Hydrogen bonded crystals (HBC) by electrophysical properties in the range of temperature $T = 50 - 450$ K, at intensities polarizing field $E_0 \approx 10^5 \div 10^6 \frac{V}{m}$, are classified as proton semiconductors and dielectrics exhibited the property of proton conductivity caused by diffusion transfer of hydrogen ions (protons) along hydrogen links towards the electric field lines [1].

For electrical industry, insulation and cable technology the certain scientific interest is in the study of the kinetics of space — charge polarization in HBC in the range of high temperature ($T = 100 - 450$ K) when the mechanism of dielectric relaxation in crystal is determined by thermally activated, and at low temperatures ($T = 50 - 100$ K), by tunneling junctions of protons [2]. This polarization type is well studied experimentally, but its theoretical description remains unsatisfactory [2, 3].

Currently, two models — microscopic and phenomenological — were applied during the investigating of processing of space charge accumulation. The first model is based on the concept of charge transfer in a multi-well potential relief and to define the space — charge distribution is necessary, in general, to solve the non-linear system of ($\approx 10^7$) equations, which is not analytically possible [2]. The solution obtained by such a system only for homogeneous low electric fields [1]. The second model is upon the description of diffusion transfer charge in the substance and it is built on the solving of the system of equations of Fokker — Planck and Poisson [2]. Since the initial phenomenological model equations are nonlinear by polarizing field, analytical solutions alone were gotten under the condition of their linearization [3].

1. The nonlinear properties of kinetic equation of proton relaxation

An analytical investigation of the influence of kinetic equation's nonlinearities [2], and establishment of the space charge relaxation mechanism on that basis will be built on the expansion of the space charge density and the dimensionless electric field $z(\xi; \tau) = \frac{E(x; t)}{E_0}$ in the non-dimensional power series [2, 3]

$$\rho(\xi; \tau) = \sum_{k=1}^{+\infty} \gamma^k \rho_k(\xi; \tau), \quad z(\xi; \tau) = \sum_{k=0}^{+\infty} \gamma^k z_k(\xi; \tau). \quad (1)$$

Turning in (1) to an expansion in the frequency harmonics $\rho^{(r\omega)}(\xi; \tau)$ we have

$$\rho(\xi; \tau) = \sum_{r=1}^{+\infty} \sum_{k=r}^{\infty} \gamma^k \rho_k^{(r\omega)}(\xi; \tau), \quad \rho(\xi; \tau) = \sum_{r=1}^{+\infty} \rho^{(r\omega)}(\xi; \tau), \quad (1.1)$$

$$\rho_k^{(r\omega)}(\xi; \tau) = \sum_{n=1}^{+\infty} \Re_k^{(r\omega)}(n, \tau) \cos\left(\frac{\pi n a}{d} \xi\right), \quad (1.2)$$

$$\rho^{(r\omega)}(\xi; \tau) = \sum_{k=r}^{\infty} \sum_{n=1}^{+\infty} \gamma^k \Re_k^{(r\omega)}(n, \tau) \cos\left(\frac{\pi n a}{d} \xi\right). \quad (1.3)$$

Function $\rho_k^{(r\omega)}(\xi; \tau)$ is multiple to frequency ($r\omega$) relaxation mode k -th order perturbation theory and $\Re_k^{(r\omega)}(n, \tau)$ — the complex amplitude of the relaxation mode n -th order (the number n of relaxation waves)

$\rho_{n,k}^{(r\omega)}(\xi; \tau) = \Re_k^{(r\omega)}(n, \tau) \cos\left(\frac{\pi n a}{d} \xi\right)$. In (1.1)–(1.3) is $\xi = \frac{x}{a}$ — a dimensionless coordinate; a — lattice constant; d — crystal thickness. Dimensionless time $\tau = W^{(0)} t$ is expressed by the zero field component of proton velocity transition probability through the potential barrier [4]

$$W^{(0)}(T) = \frac{v_0}{2} \left(\exp(-X) + \langle D^{(0)} \rangle \right), \quad \langle D^{(0)} \rangle = X \frac{\exp(-\Lambda) - \exp(-X)}{X - \Lambda}. \quad (2.1)$$

In (2) $\langle D^{(0)} \rangle$ — averaged over the energy levels of the quasi-continuous spectrum the parabolic potential barrier transparency; $X = \frac{U_0}{k_B T}$, $\Lambda = \frac{\pi \delta_0 \sqrt{m U_0}}{\hbar \sqrt{2}}$, m — proton mass; U_0 — activation energy (the height of potential barrier); v_0 — frequency of natural oscillations of the proton in the unperturbed potential well; δ_0 — width of the potential barrier [4]. Small parameter of perturbation $\gamma = \frac{\mu_{mob}^{(1)} \cdot a E_0}{D_{diff}^{(0)}}$ [3], according to expressions for the diffusion $D_{diff}^{(0)} = a^2 W^{(0)}$ and the mobility $\mu_{mob}^{(1)} = \frac{q a^2 W^{(1)}}{k_B T}$ coefficients, where q — charge of a proton [4], is expressed in terms of another small parameter $\zeta_0 = \frac{q E_0 a}{k_B T} \ll 1$ and, on condition $\frac{W^{(1)}}{W^{(0)}} < 1$, provided the form $\gamma = \frac{\zeta_0 W^{(1)}}{W^{(0)}}$. Here [4]

$$W^{(1)}(T) = \frac{v_0}{2} \left(\exp(-X) + \langle D^{(1)} \rangle \right), \quad \langle D^{(1)} \rangle = \frac{\Lambda \exp(-\Lambda) - X \exp(-X)}{X - \Lambda}. \quad (2.2)$$

The nonlinear system of equations of the phenomenological model has the form [2, 3]

$$\frac{\partial \rho}{\partial \tau} = \frac{\partial^2 \rho}{\partial \xi^2} - \theta \rho - \gamma \frac{\partial}{\partial \xi} (\rho z), \quad \frac{\partial z}{\partial \xi} = \varphi \rho, \quad (3)$$

$$\rho(\xi, 0) = 0, \quad \left. \frac{\partial \rho}{\partial \xi} \right|_{\xi=\left\{0; \frac{d}{a}\right\}} = \gamma(n_0 + \rho) z \Big|_{\xi=\left\{0; \frac{d}{a}\right\}}, \quad \int_0^{\frac{d}{a}} z(\xi; \tau) d\xi = \frac{d}{a} \exp\left(\frac{i \omega}{W^{(0)}} \tau\right). \quad (4)$$

In (3), (4) the accepted designation $\theta = \varphi \gamma n_0$, $\varphi = \frac{aq}{\epsilon_0 \epsilon_\infty E_0}$, ϵ_∞ — the high frequency dielectric permittivity of the crystal, n_0 — the equilibrium (balanced) concentration (density) of protons. In the zeroth approximation, in the expressions (1) $z_0(\tau) = \exp\left(\frac{i \omega}{W^{(0)}} \tau\right)$, $\rho_0(\xi; \tau) = 0$ are accepted [3].

We expanded $\rho_k(\xi; \tau)$ in a Fourier series of orthogonal functions $\cos\left(\frac{\pi n a}{d} \xi\right)$, on a segment $0 \leq \xi \leq \frac{d}{a}$, with an image $\mathfrak{R}_k(n, \tau) = \frac{2a}{d} \int_0^{d/a} \rho_k(\xi; \tau) \cos\left(\frac{\pi n a}{d} \xi\right) d\xi$, after transformation equations (3), (4), using (1.1), (1.2) and (1.3), we obtain the equation

$$\begin{aligned} \frac{\partial \mathfrak{R}_k(n, \tau)}{\partial \tau} + \frac{1}{\tau_n} \mathfrak{R}_k(n, \tau) &= \frac{2a}{d} \left\{ n_0 \left(z_{k-1} \Big|_{\xi=\frac{d}{a}} \cdot (-1)^n - z_{k-1} \Big|_{\xi=0} \right) - \right. \\ &\quad \left. - \frac{\pi n a}{d} \int_0^{d/a} \left(z_0 \rho_{k-1} + \sum_{m=1}^{k-2} z_m \rho_{k-m-1} \right) \sin\left(\frac{\pi n a}{d} \xi\right) d\xi \right\}, \end{aligned} \quad (5)$$

where $\frac{1}{\tau_n} = \frac{\pi^2 n^2 a^2}{d^2} + \theta$. The integral of equation (5), taking into account, is equal to

$$\begin{aligned} \mathfrak{R}_k(n; \tau) &= \left\{ -\frac{2an_0}{d} \left(1 - (-1)^n \right) \cdot \int_0^\tau z_{k-1}(0; \tau') \cdot \exp\left(\frac{\tau'}{\tau_n}\right) d\tau' - \frac{2a}{d} \cdot \frac{\pi n a}{d} \int_0^{d/a} \left(z_0 \rho_{k-1} + \sum_{m=1}^{k-2} z_m \rho_{k-m-1} \right) \times \right. \\ &\quad \left. \times \sin\left(\frac{\pi n a}{d} \xi\right) d\xi \times \exp\left(\frac{\tau'}{\tau_n}\right) \right\} \times \exp\left(-\frac{\tau}{\tau_n}\right). \end{aligned} \quad (6)$$

Further conversion function (6) lead to recurrent expression

$$\begin{aligned} \mathfrak{R}_k(n, \tau) &= \frac{8n_0 \varphi}{\pi^2} \sum_{s=1}^{\infty} \left\{ \frac{\sin^2\left(\frac{\pi s}{2}\right) \sin^2\left(\frac{\pi n}{2}\right)}{s^2} \times \left[\exp\left(-\frac{\tau}{\tau_n}\right) \cdot \int_0^\tau \mathfrak{R}_{k-1}(s, \tau') \exp\left(\frac{\tau'}{\tau_n}\right) d\tau' \right] \right\} - \\ &- \frac{4a}{d} \cdot \sum_{s=1}^{\infty} \left\{ \frac{n^2 \cos^2\left(\frac{\pi n}{2}\right) \sin^2\left(\frac{\pi s}{2}\right)}{n^2 - s^2} \times \left[\exp\left(-\frac{\tau}{\tau_n}\right) \cdot \int_0^\tau \mathfrak{R}_{k-1}(s, \tau') \exp\left(\left(i \frac{\omega}{W^{(0)}} + \frac{1}{\tau_n}\right) \tau'\right) d\tau' \right] \right\} + \\ &+ \frac{8\varphi}{\pi^2} \sum_{m=1}^{k-2} \sum_{p=1}^{\infty} \sum_{l=1}^{\infty} \left\{ \frac{n^2 \cos^2\left(\frac{\pi n}{2}\right) \sin^2\left(\frac{\pi p}{2}\right) \sin^2\left(\frac{\pi l}{2}\right)}{l^2 (n^2 - p^2)} \cdot \int_0^\tau \mathfrak{R}_{k-m-1}(p, \tau') \mathfrak{R}_m(l, \tau') \exp\left(\frac{\tau'}{\tau_n}\right) d\tau' \right\} \times \\ &\quad \times \exp\left(-\frac{\tau}{\tau_n}\right). \end{aligned} \quad (7)$$

The first term of the integrand in recurrence formula (7) describes the interactions between the relaxation modes different number n of the same order k and leads only to increased amplitudes of the modes in the odd frequency harmonics. The second and third terms of this expression describes the effect of the interaction of different modes and the number n and order k , and lead to the excitation $(k-1)\omega$, $k\omega$ — harmonics appropriately. According to (7) odd harmonic frequency relaxation modes contain odd numbers k , and even harmonics — even — k . Thus, the contribution to the dipole moment of the dielectric gives only odd harmonic frequency, etc. The nonlinear interaction relaxation modes have a significant influence on the formation of the space charge at the frequency ω only at the initial stage when $t \leq \tau_1$ relaxation time fashion with $k = 1$. Determine the complex amplitudes $\mathfrak{R}_k(n, \tau)$ in analytical form at times $t \leq \tau_1$ fails, however, when executed in the art $\tau \gg \tau_1$, provided the relaxation process becomes stationary, periodic and relaxation terms in the expression (7) can be neglected. Since they measure the dielectric losses when losses are connected to the fundamental frequency, it is necessary to determine the complex amplitude $\mathfrak{R}_k^{(\omega)}(n, \tau)$ at this

frequency. Since generation of relaxation modes with complex amplitudes begins with the first-order perturbation theory [2, 3]

$$\Re_1^{(\omega)}(n, \tau) = -\frac{4an_0}{d} \times \sin^2\left(\frac{\pi n}{2}\right) \times \frac{\exp\left(i\frac{\omega}{W^{(0)}}\tau\right)}{\frac{1}{\tau_n} + i\frac{\omega}{W^{(0)}}}, \quad (8.1)$$

of the first term of (7) is easily visible

$$\Re_2^{(\omega)}(n, \tau) = -\frac{4an_0}{d} \times \frac{8n_0\varphi}{\pi^2} \times \sin^2\left(\frac{\pi n}{2}\right) \times \sum_{s=1}^{\infty} \frac{\sin^2\left(\frac{\pi s}{2}\right)}{s^2\left(\frac{1}{\tau_s} + i\frac{\omega}{W^{(0)}}\right)} \times \frac{\exp\left(i\frac{\omega}{W^{(0)}}\tau\right)}{\frac{1}{\tau_n} + i\frac{\omega}{W^{(0)}}}, \quad (8.2)$$

$$\Re_3^{(\omega)}(n, \tau) = -\frac{4an_0}{d} \times \left(\frac{8n_0\varphi}{\pi^2}\right)^2 \times \sin^2\left(\frac{\pi n}{2}\right) \times \left(\sum_{s=1}^{\infty} \frac{\sin^2\left(\frac{\pi s}{2}\right)}{s^2\left(\frac{1}{\tau_s} + i\frac{\omega}{W^{(0)}}\right)} \right)^2 \times \frac{\exp\left(i\frac{\omega}{W^{(0)}}\tau\right)}{\frac{1}{\tau_n} + i\frac{\omega}{W^{(0)}}}, \quad (8.3)$$

from which we obtain the recurrence formula

$$\Re_k^{(\omega)}(n, \tau) = -\frac{4an_0}{d} \times \left(\frac{8n_0\varphi}{\pi^2}\right)^{k-1} \times \sin^2\left(\frac{\pi n}{2}\right) \times \Lambda_0^{k-1} \times \frac{\exp\left(i\frac{\omega}{W^{(0)}}\tau\right)}{\frac{1}{\tau_n} + i\frac{\omega}{W^{(0)}}}. \quad (9)$$

$$\text{In (9)} \quad \Lambda_0 = \sum_{s=1}^{\infty} \frac{\sin^2\left(\frac{\pi s}{2}\right)}{s^2\left(\frac{1}{\tau_s} + i\frac{\omega}{W^{(0)}}\right)}.$$

From (1.3), when $r = 1$, we have

$$\rho^{(\omega)}(\xi; \tau) = \sum_{k=1}^{\infty} \sum_{n=1}^{+\infty} \gamma^k \Re_k^{(\omega)}(n, \tau) \cos\left(\frac{\pi n a}{d} \xi\right). \quad (10)$$

Substituting (9) to (10) gives a final

$$\rho^{(\omega)}(\xi, \tau) = -\frac{4an_0\gamma}{d\left(1 - \frac{8\varphi n_0 \Lambda_0 \gamma}{\pi^2}\right)} \times \sum_{n=1}^{+\infty} \left[\frac{\sin^2\left(\frac{\pi n}{2}\right)}{\frac{1}{\tau_n} + i\frac{\omega}{W^{(0)}}} \right] \times \cos\left(\frac{\pi n a}{d} \xi\right) \times \exp\left(\frac{i\omega\tau}{W^{(0)}}\right). \quad (11)$$

From (1.2), when $r = 1$, when

$$\rho_k^{(\omega)}(\xi; \tau) = \sum_{n=1}^{+\infty} \Re_k^{(\omega)}(n, \tau) \cos\left(\frac{\pi n a}{d} \xi\right), \quad (12)$$

considering (9), we have

$$\begin{aligned} \rho_k^{(\omega)}(\xi, \tau) &= -\frac{4an_0}{d} \cdot \frac{8^{k-1} a^{k-1} q^{k-1} n_0^{k-1}}{\pi^{2(k-1)} \varepsilon_0^{k-1} \varepsilon_{\infty}^{k-1} E_0^{k-1}} \times \exp\left(\frac{i\omega\tau}{W^{(0)}}\right) \times \\ &\times \sum_{n_1=1}^{\infty} \sum_{n_2=1}^{\infty} \dots \sum_{n_k=1}^{\infty} \left(\frac{\sin^2\left(\frac{\pi n_1}{2}\right) \cdot \sin^2\left(\frac{\pi n_2}{2}\right) \cdot \dots \cdot \sin^2\left(\frac{\pi n_k}{2}\right)}{n_2^2 \cdot \dots \cdot n_k^2 \left(\frac{1}{\tau_{n_1}} + i\frac{\omega}{W^{(0)}}\right) \left(\frac{1}{\tau_{n_2}} + i\frac{\omega}{W^{(0)}}\right) \cdot \dots \cdot \left(\frac{1}{\tau_{n_k}} + i\frac{\omega}{W^{(0)}}\right)} \right) \cos\left(\frac{\pi n_1 a}{d} \xi\right). \end{aligned} \quad (13)$$

From (1.1), when $r = 1$, when

$$\rho^{(\omega)}(\xi; \tau) = \sum_{k=1}^{\infty} \gamma^k \rho_k^{(\omega)}(\xi; \tau), \quad (14)$$

taking into account (13), we obtain (11).

2. Non-linear polarization effects

Polarization at the fundamental frequency $P^{(\omega)}(\xi, \tau) = qx \cdot \rho^{(\omega)}(\xi, \tau)$, averaged over the thickness of the dielectric

$$P^{(\omega)}(\tau) = \frac{q}{d} \int_0^d x \rho^{(\omega)}(\xi, \tau) dx, \quad (15)$$

according to (11) it takes the form

$$P^{(\omega)}(\tau) = \frac{8aqn_0 \gamma}{\pi^2 \left(1 - \frac{8aqn_0 \Lambda_0 \gamma}{\pi^2 \epsilon_0 \epsilon_\infty E_0} \right)} \times \sum_{n=1}^{+\infty} \left[\frac{\sin^2 \left(\frac{\pi n}{2} \right)}{n^2 \left(\frac{1}{\tau_n} + i \frac{\omega}{W^{(0)}} \right)} \right] \times \exp \left(\frac{i \omega \tau}{W^{(0)}} \right). \quad (16)$$

Averaging k -th polarization components

$$P_k^{(\omega)}(\tau) = \frac{q}{d} \int_0^d x \rho_k^{(\omega)}(\xi, \tau) dx, \quad (17)$$

taking into account (11) it gives

$$P_k^{(\omega)}(\tau) = \frac{8^k a^k q^k n_0^k}{\pi^{2k} \epsilon_0^{k-1} \epsilon_\infty^{k-1} E_0^{k-1}} \sum_{n_1=1}^{\infty} \dots \sum_{n_k=1}^{\infty} \left[\frac{\sin^2 \left(\frac{\pi n_1}{2} \right) \dots \sin^2 \left(\frac{\pi n_k}{2} \right) \times \exp \left(\frac{i \omega}{a_0} \tau \right)}{n_1^2 \cdot n_2^2 \cdot \dots \cdot n_k^2 \cdot \left(\frac{1}{\tau_{n_1}} + i \frac{\omega}{W^{(0)}} \right) \cdot \dots \cdot \left(\frac{1}{\tau_{n_k}} + i \frac{\omega}{W^{(0)}} \right)} \right]. \quad (18)$$

Substituting (14) into (15)

$$P^{(\omega)}(\tau) = \sum_{k=1}^{\infty} \gamma^k P_k^{(\omega)}(\tau), \quad (19)$$

taking (18) confirms the expression (16).

As seen from the functions (13), (18), at the first odd field frequency (ω) manifest the nonlinear polarization phenomena is associated with the interaction relaxation modes of the same order perturbation theory ($k = 1$), differing in number n_k . The relaxation times for these modes $\tau_{n_1}, \tau_{n_2}, \dots, \tau_{n_k}$. Obviously, a small parameter γ of linear solution of the Fokker - Planck [2, 3] is a special case of solutions of the generalized primary field frequency (ω) (11). Thus, a generalized formula for the polarization of the dielectric (16) in

the first-order perturbation theory ($k = 1$) when $\sum_{k=1}^{\infty} \left(\frac{8\varphi n_0 \Lambda_0 \gamma}{\pi^2} \right)^{k-1} = \frac{1}{1 - \frac{8\varphi n_0 \Lambda_0 \gamma}{\pi^2}} \rightarrow 1$, proceeds to the result [2].

Conclusions

1. The influence of the nonlinearities of the kinetic equation of proton relaxation for mechanism of volumetric - charge polarization in proton semiconductors and dielectrics is investigated. From the solution of the nonlinear system of the equations of Fokker - Planck and Poisson (3), (4), recurrence formula for the complex amplitudes $\mathfrak{R}_k(n, \tau)$ of the relaxation mode number n in the k -th order perturbation theory is built (7).

2. By methods of quasiclassical kinetic theory it is proved that the forming space - charge polarization in the class HBC crystals in an alternating electric field only odd powers of the field relaxation harmonic $\rho^{((2\lambda+1)\omega)}(\xi; \tau) \sim E^{2\lambda+1}(t)$ are generated in an external circuit. The generalized expression (16) is retrieved

on the fundamental frequency of the alternating field (ω) for the polarization HBC with blocking contacts at the boundaries of the dielectric.

3. It is found that already at the first odd field frequency (ω) nonlinear effects caused by the interaction of different number n_k relaxation modes $k = 1$ order perturbation theory (equation (13), (18)).

Механизм нелинейной объемно-зарядовой поляризации в твердых диэлектриках

Методами кинетической теории исследуются нелинейные кинетические явления при формировании объемно-зарядовой поляризации в кристаллах с водородными связями (КВС). Из решения нелинейной системы уравнений Фоккера – Планка и Пуассона при блокирующих электродах установлено, что при математическом описании релаксационной поляризации в КВС в области слабых полей (100–1000 кВ/м) и высоких температур ($T > 350$ К) можно ограничиться первым приближением теории возмущений. Аналитически установлено, что на основной частоте переменного поля начинают проявляться нелинейные эффекты, обусловленные взаимодействием отличающихся по номеру n релаксационных мод. Коэффициенты диффузии и подвижности вычисляются с учетом обоих механизмов переходов (термически активируемых и туннельных) протонов через параболический потенциальный барьер. Протон-протонное и протон-фононное взаимодействия не рассматриваются. Предложенная схема решения кинетического уравнения может быть применена и к другим, схожим с КВС по типу и свойствам кристаллической решетки, кристаллам с ионной проводимостью.

Ключевые слова: протонные полупроводники и диэлектрики; кристаллы с водородными связями (КВС); протонная релаксация и проводимость; нелинейная система уравнений Фоккера–Планка и Пуассона; релаксационные моды; поляризационные частотные гармоники.
